SOME LOCAL CONVEXITY THEOREMS FOR THE ZETA-FUNCTION-LIKE ANALYTIC FUNCTIONS

R. Balasubramanian and K. Ramachandra

§ 1. INTRODUCTION. Suppose \( f(s) \) is an analytic function of \( s = \sigma + it \) defined in the rectangle \( R = \{a \leq \sigma \leq b, t_0 - H \leq t \leq t_0 + H\} \) where \( a \) and \( b \) are constants with \( a < b \). We assume that \( |f(s)| \leq M \) (with \( M \geq 2 \) sometimes we assume implicitly that \( M \) exceeds a large positive constant) throughout \( R \). We are interested in the question of lower bounds for

\[
I(\sigma) = \int_{|w| \leq H} |f(\sigma + it_0 + iw)|^k \, dw
\]

where \( k > 0 \) is a real constant. The method we employ is very much related to the methods of our paper [1] in combination with the results in the appendix to [5]. Some of our results regarding (1) are improvements of some lemmas in Ivić's book [3] (see page 172 of this book). It should be mentioned that our results (though of some interest in themselves) do not give any new important applications except (5),(6) and (7). In § 2 we prove a general result on local-convexity from which the following theorem is a consequence. (All our constants will be effective and we do not state this fact every time).

THEOREM 1. Suppose there exists a constant \( d \) such that \( a < d < b \) and that in \( d \leq \sigma \leq b, |f(s)| \) is bounded below and above by \( \beta \) and \( \beta^{-1} \) where \( \beta \leq 1 \) is a positive constant, (it is enough to assume this condition for
We next prove a δ-convexity theorem which is simply this.

**THEOREM 2.** Let \( A_0, \sigma_1, \delta \) be any three constants satisfying \( A_0 > 0, a < \sigma_1 < b \) and \( \delta > 0 \) and let \( H = \delta \). Then we have, with \( \sigma = \sigma_1 + (\log M)^{-1} \), the inequality

\[
| f(\sigma + it_0) |^k \ll M^{-A_0} + I(\sigma) \log M.
\]

Also, we have,

\[
\int_{|w| \leq \delta / 2} | f(\sigma + it_0 + iw) |^k \, dw \ll M^{-A_0} + I(\sigma) \log \log M.
\]

we have also similar results with \( \sigma^* = \sigma_1 - (\log M)^{-1} \) in place of \( \sigma \).

The third of our theorems is

**THEOREM 3.** Let \( \sigma_1 \) be a constant satisfying \( a < \sigma_1 < b \) and \( H \) be a large constant depending on other constants. Then we have (with any large positive constant \( A_0 \) and any constant \( k > 0 \))

\[
| f(\sigma_1 + it_0) |^k \ll M^{-A_0} + I(\sigma_1) \log M
\]

and because of Theorem 1, we have, (assuming on \( f(s) \) the conditions of Theorem 1) the inequality

\[
| f(\sigma_1 + it_0) |^k \ll I(\sigma_1) \log M.
\]

For a remark on equations marked with an asterisk see the post-script at the end.

Theorems 1 to 3 have immediate applications to \( \zeta(s) \) and \( L \)-functions we can take for example \( f(s) = \zeta(s) \) and we obtain the following theorem as a corollary. We state only two applications of each of these theorems.

**THEOREM 4.** Let \( k \) and \( \epsilon \) be any two positive constants, \( A_0 \) any large
positive constant, \( \sigma \) a constant satisfying \( 1/2 \leq \sigma \leq 1 \). Then, we have, for \( t_0 \geq 10 \) and \( D \) a certain large positive constant,

\[
\int_{|w| \leq D} |\zeta(\sigma + it_0 + iv)|^k \, dv \gg t_0^{-\varepsilon}. \tag{5}
\]

Combining this with the functional equation we obtain,

\[
\int_{|w| \leq D} |\zeta(\sigma - 1/2 + it_0 + iv)|^k \, dv \gg t_0^{k(1-\sigma)-\varepsilon}. \tag{6}
\]

Also

\[
\int_{|w| \leq D} |\zeta(1 + it_0 + iv)|^k \, dv \gg (\log t_0)^{-\varepsilon} \tag{7}
\]

and here we can (if we assume Riemann Hypothesis) replace RHS by \((\log \log t_0)^{-\varepsilon}\).

Next, we have

\[
|\zeta(\sigma + it_0)|^k \ll t_0^{-A_0} + (\log t_0) \int_{|w| \leq \delta} |\zeta(\sigma + (\log t_0)^{-1} + it_0 + iv)|^k \, dv \tag{8}
\]

and the same inequality holds if we replace on the RHS \((\log t_0)^{-1}\) by \(-(\log t_0)^{-1}\). Finally

\[
|\zeta(\sigma + it_0)|^k \ll (\log t_0) \int_{|w| \leq D} |\zeta(\sigma + it_0 + iv)|^k \, dv. \tag{9} \quad \text{(9)}
\]

Next we can apply our method to other problems such as proving that the large values of \(|\zeta(s)|\) are "rare" in a certain sense providing an alternative approach to some results of A. Ivčić [4]. More specifically we prove

**Theorem 5.** Let \( \alpha_0 \) be a small positive constant and let \( t_0 \) exceed a sufficiently large positive constant and \( \alpha_0 \geq \delta \geq (\log t_0)^{-3/4} \). Let \( s_1 = 1 + it_0, s_0 = \sigma_0 + it_1 \) where \( 0 \leq 1 - \sigma_0 \leq \delta \) and \( |t_1 - t_0| \leq \delta \). Suppose that for \( |s_1 - s| \leq 20\delta \) we have \( \zeta(s) \neq 0 \). Then

\[
|\zeta(\sigma_0 + it_1)| \ll \exp(Z^{1-\alpha_0} (\log \log Z + 1)) \tag{10}
\]

where

\[
Z = \exp\left(\frac{10}{\delta} \log \log t_0 + \frac{13}{\delta}\right). \tag{11}
\]

**Remark.** This theorem can be generalised very much by our method for example to \( \zeta \)-functions and \( L \)-functions of number fields.
Before concluding this section we make a few remarks. In a series of papers the second of us started with the kernel function \( E_p(\sin z)^2 \) and made extensive use of this kernel proving a number of convexity results over short intervals. Some of them are (with \( H \gg \log \log M \) with a suitable implied constant) that we can replace the RHS in (2) by \( H \). Also he proved (\( H \) subject to the same condition) things like

\[
\frac{1}{H} \int_{|\omega| \leq H} |\zeta(\frac{1}{2} + it_0 + i\omega)|^{2k} \, d\omega \gg (\log H)^{k^2}
\]

where \( k > 0 \) is any rational constant. (With \( k = \frac{1}{2} \) this was first proved by Ramachandra [7]. Next Heath-Brown proved this with \( k > 0 \) any rational constant and \( H = t_0 \) [2].) Next Ramachandra extended Heath-Brown's result to \( t_0 \geq H \gg \log \log t_0 \). For positive irrational constants \( k \) Ramachandra proved [8], subject to the same conditions on \( H \), the result

\[
\frac{1}{H} \int_{|\omega| \leq H} |\zeta(\frac{1}{2} + it_0 + i\omega)|^{2k} \, d\omega \gg \left(\frac{\log H}{\log \log H}\right)^{k^2}.
\]

Later he proved a stronger result [9] where RHS here was replaced by a bigger function depending on the simple continued fraction expansion of \( k \).

§ 2. A GENERAL RESULT ON LOCAL CONVEXITY.

First of all a remark about the real constant \( k > 0 \). We will (for technical simplicity) assume that \( k \) is an integer. To prove the general case we have to proceed as we do in this section and to use the Riemann mapping theorem (with zero cancelling factors for a certain rectangle i.e. \( \theta(w) \)) as given in the appendix to [5] (see Lemmas 2,3 and 4 of the appendix). If \( k \) is an integer we can consider \( f(s) \) in place of \( (f(s))^k \) without loss of generality.

Let \( a \leq \sigma_0 < \sigma_1 < \sigma_2 \leq b, 0 < D \leq H, \sigma_1 + it_0 \) and let \( P \) denote the contour \( P_1P_2P_3P_4P_1 \) where \( P_1 = -(\sigma_1 - \sigma_0) + iD, P_2 = \sigma_2 - \sigma_1 + iD, P_3 = \sigma_2 - \sigma_1 + iD \) and \( P_4 = -(\sigma_1 - \sigma_0) + iD \). Let \( w = u + iv \) be a complex variable. We have

\[
2\pi i f(s_1) = \int_P f(s_1 + w)X^u \frac{dw}{w} \text{ where } X > 0.
\]

We put

\[
X = \exp(Y + u_1 + u_2 + \ldots + u_r)
\]
Local Convexity Theorems

where \( Y \geq 0 \) and \((u_1, u_2, ..., u_r)\) is any point belonging to the \( r \)-dimensional cube \([0, C] \times [0, C] \times ... \times [0, C], C\) being a positive constant to be chosen later. The contour \( P \) consists of the two vertical lines \(-V_0 \) and \( V_2 \) respectively given by \( P_4 P_1 \) and \( P_3 P_2 \) and two horizontal lines \( Q_1, Q_2 \) respectively given by \( P_1 P_2 \) and \( P_3 P_4 \). Averaging the equation (12) over the cube we get

\[
2\pi i f(s_1) = C^{-r} \int_0^C \int_0^C \int_P f(s_1 + w) \frac{X^w}{w} \, dw \, du_1 \, du_r. \tag{14}
\]

Over \( V_0 \) and \( V_2 \) we do not do the averaging. But over \( Q_1 \) and \( Q_2 \) we do average and replace the integrand by its absolute value. We obtain

\[
|2\pi f(s_1)| \leq \text{Exp}(-Y(\sigma_1 - \sigma_0)) f_V |f(s_1 + w)| \, dw \]
\[
+ \text{Exp}(Y + Cr)(\sigma_2 - \sigma_1) f_{V_2} |f(s_1 + w)| \, dw \]
\[
+ \frac{2^{r+1}}{C^2} \text{Exp}(Y + Cr)(\sigma_2 - \sigma_1)(\max_{w \in Q_1, Q_2} |f(s_1 + w)|)(\sigma_2 - \sigma_0)
\]

and thus

\[
|2\pi f(s_1)| \leq \left( \text{Exp}(-Y(\sigma_1 - \sigma_0)) \right) I_0
\]
\[
+ \left( \text{Exp}(Cr(\sigma_2 - \sigma_1))\left( \text{Exp}(Y(\sigma_2 - \sigma_1)) \right)(I_2 + M^{-A})
\]
\[
+ 2M(\sigma_2 - \sigma_0)(\text{Exp}(Y(\sigma_2 - \sigma_1)))(2 \text{Exp}(Cr(\sigma_1 - \sigma_0))^r
\]

where \( A \) is any positive constant and

\[
I_0 = \int_{V_0} |f(s_1 + w)| \, dw \quad \text{and} \quad I_2 = \int_{V_2} |f(s_1 + w)| \, dw.
\tag{16}
\]

Choosing \( Y \) to equalise the first two terms on the RHS of (15), i.e. choose \( Y \) by

\[
\text{Exp}(Y(\sigma_2 - \sigma_0)) = \left( \frac{I_0}{I_2 + M^{-A}} \right)^{\sigma_2 - \sigma_1}(\sigma_2 - \sigma_0)^{-1} \text{Exp}(-C r(\sigma_2 - \sigma_1)^{2}(\sigma_2 - \sigma_0)^{-1})
\]

and noting that

\[
(\sigma_2 - \sigma_1) - (\sigma_2 - \sigma_1)^2(\sigma_2 - \sigma_0)^{-1} = (\sigma_2 - \sigma_1)(\sigma_1 - \sigma_0)(\sigma_2 - \sigma_0)^{-1}
\]

we obtain

\[
|2\pi f(s_1)| \leq 2 \left[ \frac{I_0}{I_2 + M^{-A}} \right]^{\sigma_2 - \sigma_1}(\sigma_2 - \sigma_0)^{-1} \left\{ \text{Exp}(\frac{C(\sigma_2 - \sigma_1)(\sigma_1 - \sigma_0)}{\sigma_2 - \sigma_0}) \right\} r
\]
\[
+ 2M(\sigma_2 - \sigma_0)(\frac{I_0}{I_2 + M^{-A}})^{\sigma_2 - \sigma_1}(\sigma_2 - \sigma_0)^{-1} \left\{ \frac{2}{C^2} \text{Exp}(\frac{C(\sigma_2 - \sigma_1)(\sigma_1 - \sigma_0)}{\sigma_2 - \sigma_0}) \right\} r. \tag{17}
\]
Collecting we state the following convexity theorem.

**Theorem 6.** Suppose \( f(s) \) is an analytic function of \( s = \sigma + it \) defined in the rectangle \( R : \{ a \leq \sigma \leq b, t_0 - H \leq t \leq t_0 + H \} \) where \( a \) and \( b \) are constants with \( a < b \). Let the maximum of \( |f(s)| \) taken over \( R \) be \( \leq M \). Let \( a \leq \sigma_0 < \sigma_1 < \sigma_2 \leq b \) and let \( A \) be any large positive constant. Let \( r \) be any positive integer, \( 0 < D \leq H \) and \( s_1 = \sigma_1 + it_0 \). Then for any positive constant \( C \), we have,

\[
|2\pi f(s_1) - 2\pi f(s_2) - 2\pi f(s_3)| \leq \frac{2\pi}{\left| \frac{C(\sigma_2 - \sigma_1)(\sigma_2 - \sigma_0)}{\sigma_2 - \sigma_0} \right|^r} \left\{ \left| \frac{\exp(\frac{C(\sigma_2 - \sigma_1)(\sigma_2 - \sigma_0)}{\sigma_2 - \sigma_0})}{\sigma_2 - \sigma_0} \right|^r + 2M^{r+2}(\sigma_2 - \sigma_0)(2(1 + (\log(\frac{D}{\sigma_1 - \sigma_0}))^r)\sigma_2 - \sigma_1)(\sigma_2 - \sigma_0)^{-1} \times \left\{ \frac{2}{D} \exp(\frac{C(\sigma_2 - \sigma_1)(\sigma_2 - \sigma_0)}{\sigma_2 - \sigma_0}) \right\}^r \right\}
\]

where

\[
I_0 = \int_{|\alpha| \leq D} \left| f(\sigma_0 + it_0 + iv) \frac{dv}{\sigma_0 - \sigma_1 + iv} \right| \quad (19)
\]

and

\[
I_2 = \int_{|\alpha| \leq D} \left| f(\sigma_1 + it_0 + iv) \frac{dv}{\sigma_2 - \sigma_1 + iv} \right| \quad (20)
\]

and we have written \( (x)^r = \max(0,x) \) for any real number \( x \).

**Proof.** We have used \( I_2 + M^{-A} \geq M^{-A} \) and \( (\sigma_2 - \sigma_1)(\sigma_2 - \sigma_0)^{-1} \leq 1 \) and if \( D \geq \sigma_1 - \sigma_0 \),

\[
I_0 \leq M \int_{|\alpha| \leq D} \left| \frac{dv}{\sigma_0 - \sigma_1 + iv} \right| \leq 2M \left\{ \int_{0}^{\sigma_1 - \sigma_0} \frac{dv}{\sigma_1 - \sigma_0} + \int_{\sigma_1 - \sigma_0}^{D} \frac{dv}{\sigma_1 - \sigma_0} \right\}
\]

This completes the proof of Theorem 6.

In (18) we replace \( t_0 \) by \( t_0 + \alpha \) and integrate with respect to \( \alpha \) in the range \( |\alpha| \leq D \), where now \( 2D \leq H \). LHS is now \( I(\sigma_1) \) defined by

\[
J(\sigma_1) = 2\pi \int_{|\alpha| \leq D} |f(\sigma_1 + it_0 + i\alpha)| \, d\alpha.
\]

Next

\[
J(\sigma_1) \leq \left( \int_{|\alpha| \leq D} \right) (\sigma_2 - \sigma_1)(\sigma_2 - \sigma_0)^{-1} \left( \int_{|\alpha| \leq D} \right) (\sigma_2 - \sigma_0)(\sigma_2 - \sigma_0)^{-1}.
\]
Local Convexity Theorems

Now
\[
\int_{|x| \leq D} I(x) \, dx = \int_{|x| \leq D} \int_{|y| \leq D} |f(x + iy)\frac{dx \, dy}{\sigma_0 - x + iy}| \\
\leq (\int_{|x| \leq 2D} |f(x)\frac{dx}{\sigma_0 - x + iy}| \int_{|y| \leq D} |\frac{dy}{\sigma_0 - x + iy}| \\
\leq 2(1 + (\log(\frac{D}{\sigma_0 - \sigma_0}))^*) I(\sigma_0)
\]
(22)

where
\[
I(\sigma_0) = \int_{|x| \leq 2D} |f(x)\frac{dx}{\sigma_0 - x + iy}| \, dy.
\]
(23)

Proceeding similarly, with
\[
I(\sigma_2) = \int_{|x| \leq 2D} |f(x + iy)\frac{dx \, dy}{\sigma_0 - x + iy}| \\
\]
we have
\[
\int_{|x| \leq D} (I_2 + M^{-A}) \, dx \leq 2DM^{-A} + 2(1 + (\log(\frac{D}{\sigma_0 - \sigma_0}))^*) I(\sigma_2).
\]
(25)

Thus we have the following corollary.

**Theorem 7.** In addition to the conditions of Theorem 6, let $2D \leq H$ and let $J(\sigma_1), I(\sigma_0)$ and $I(\sigma_2)$ be defined by (21), (23) and (24). Then, we have,

\[
2\pi J(\sigma_1) \leq 4\{I(\sigma_0)(1 + (\log(\frac{D}{\sigma_0 - \sigma_0}))^*)(\sigma_2 - \sigma_1)(\sigma_2 - \sigma_0)^{-1} \times \\
\times \{I(\sigma_2)(1 + (\log(\frac{D}{\sigma_0 - \sigma_0}))^*) + M^{-A}\}(\sigma_1 - \sigma_0)(2 - \sigma_0)^{-1} \times \\
\times \{\text{Exp}\left(\frac{C(\sigma_2 - \sigma_1)(\sigma_1 - \sigma_0)}{\sigma_2 - \sigma_0}\right)\}^r + 4M^{A电视剧} + 2(1 + (\log(\frac{D}{\sigma_0 - \sigma_0}))^*)(\sigma_2 - \sigma_1)(\sigma_2 - \sigma_0)^{-1} \times \\
\times \{\text{Exp}\left(\frac{C(\sigma_2 - \sigma_1)(\sigma_1 - \sigma_0)}{\sigma_2 - \sigma_0}\right)\}^r \}
\]
(26)

3. **Proof of Theorem 1.** In Theorem 7 replace $D$ by $D/2$ and assume that $J(\sigma_1)$ is bounded below (by $\frac{1}{2} D$) and $I(\sigma_2)$ is bounded above by $\beta^{-1} D$ (these conditions are implied by the conditions of Theorem 1). Put $\gamma = 1, r = [\log M] + 1$ and $D = E\text{Exp}\left(e^{-1}E\right)$ where $E$ is a large constant. Let $\sigma_0, \sigma_1$ and $\sigma_2$ be constants satisfying $a \leq \sigma = \sigma_0 < \sigma_1 < \sigma_2 \leq b$. We see that the second term on the RHS of (26) is $\leq M^{-A}$ so that

\[
\frac{1}{2} \beta D \leq J(\sigma_1) \leq 4\{I(\sigma_0)(1 + (\log(\frac{D}{\sigma_0 - \sigma_0}))^*)(\sigma_2 - \sigma_1)(\sigma_2 - \sigma_0)^{-1} \times \\
\times \{\beta^{-1} D(1 + (\log(\frac{D}{\sigma_0 - \sigma_0}))^*)\}(\sigma_1 - \sigma_0)(\sigma_2 - \sigma_0)^{-1} \times \{\text{Exp}(\frac{C(\sigma_2 - \sigma_1)(\sigma_1 - \sigma_0)}{\sigma_2 - \sigma_0})\}^r \}
\]
(27)
This proves Theorem 1.

§ 4. δ-CONVEXITY AND PROOF OF THEOREM 2. In theorems 6 and 7 choose \( \theta = \delta \) (\( \delta \) any positive constant), \( \sigma_2 - \sigma_1 = (\log M)^{-1}, \sigma_2 = \sigma, \sigma_0 = a, r = [\log M], K = \text{a large constant times } \delta^{-1}. \) We obtain the first part of Theorem 2 namely (3) and (3'). To obtain the second part we argue as in the proof of Theorems 6 and 7 but now with

\[
\frac{1}{2\pi i} \int f(s_1 + w)X^{-w} \frac{dw}{w}
\]

along the same contour \( P \) with the same \( X \) as before (note \( X^{-w} \) in the present integrand). The rest of the details are similar.

§ 5. PROOF OF THEOREM 3. We follow closely the notation of § 2. We now put \( \sigma_0 = a, \sigma_2 = b. \) Now consider the integral

\[
\frac{1}{2\pi i} \int_{\text{Re } w = b - \sigma_1, |\text{Im } w| \leq H} f(s_1 + w)X^{-w} \frac{dw}{w}. \tag{28}
\]

This is \( O(M^{-A}) \) provided \( X \) exceeds a suitable power of \( M. \) On the other hand, the integral

\[
\frac{1}{2\pi i} \int f(s_1 + w)X^w \frac{dw}{w} \tag{29}
\]

over the same path equals

\[
f(s_1) + \frac{1}{2\pi i} \left( \int_{H_1} + \int_{H_2} + \int_V \right) f(s_1 + w)X^w \frac{dw}{w} \tag{30}
\]

where \( s_1 + w \) runs over the paths \( H_1, H_2 \) and \( V \) where \( H_1 \) and \( H_2 \) are the horizontal sides of \( R \) and \( V \) is the left vertical line boundary of \( R. \) (The contribution from \( V \) is \( O(M^{-A}) \) if \( X \) is a large power of \( M). \) Hence

\[
\frac{1}{2\pi i} \int f(s_1 + w)(X^w - X^{-w}) \frac{dw}{w} \tag{31}
\]

taken over the path in (28) (same as for (29) also) equals the integral (29) plus \( O(M^{-A}). \) Now move the line of integration to \( \text{Re } w = 0 \) and do the averaging as before writing \( X = \exp(Y + u_1 + \ldots + u_r) \) and we are led to the proof of Theorem 3.

§ 6. ANOTHER APPLICATION OF OUR METHOD. In this section we prove Theorem 5 (our proof is quite general and goes through for zeta and \( L \)-functions of algebraic number fields and so on). We need from
Local Convexity Theorems

Titchmarsh's book [10] (see § 5.5, pages 174-175) the following theorem (we state it in the notation of this book).

**THEOREM 8 (BOREL-CARATHEODORY).** Let \( f(z) \) be analytic in \( |z| \leq R \) and \( M(r) \) denote the maximum of \( |f(z)| \) in \( |z| \leq r < R \). Let \( A(R) \) denote the maximum of the real part of \( f(z) \) on \( |z| = R \). Then

\[
M(r) \leq \frac{2r}{R-r} A(R) + \frac{R+r}{R-r} |f(0)|.
\]

We now take \( f(z) \) to be \( \log \zeta(s_1 + z) \). We will assume that \( t_0 \) exceeds a large constant. It is not hard to prove that \( \log \zeta(s_1) = O(\log \log t_0) \). Taking \( R = 20\delta, r = 19\delta \) we see that in \( |z| \leq 19\delta \) we have \( |\log \zeta(s_1 + z)| \leq 800 \delta \log t_0 \).

Let now \( |t_0 - t_1| \leq \delta \) and \( 1 - \delta \leq \sigma_0 \leq 1 \). (We now use a notation not to be confused with the earlier one). Let \( P_1 = 1 + \frac{1}{2}it_0, P_2 = s_1 - 4i\delta, P_3 = 1 - 4\delta + it_0 - 4i\delta, P_4 = 1 - 4\delta + it_0 + 4i\delta, P_5 = s_1 + 4i\delta, P_6 = 1 + 2it_0 \).

Let \( P \) denote the contour \( P_1P_2P_3P_4P_5P_6P_1 \). Put \( X = \text{Exp}(Y + u_1 + u_2 + \ldots + u_r) \) where \( (u_1, \ldots, u_r) \) is as before with the earlier notation. Averaging over the cube we have

\[
\frac{1}{2\pi} \int \ldots \int \log \zeta(s_0 + w) \frac{X^w}{w} dw du_1 \ldots du_r \leq \frac{C-r}{C-r} + 10.
\]

The contribution (to the integral involving \( \zeta(s_0 + w) \)) from \( P_3P_4 \) has absolute value \( \leq 10 \) if \( \text{Exp}(Y\delta) \geq 800 \log t_0 \).

To satisfy this we put \( Y = \frac{1}{6} (\log \log t_0 + 13) \). The average over other parts of the same integral has absolute value

\[
\leq 800(\delta \log t_0)(\frac{2}{C\delta}) Y \text{Exp}(Y + Cr)(1 - \sigma_0)).
\]

We put \( C = \frac{9}{6} \) and \( r = [\log \log t_0] \), so that this expression is

\[
\leq \varepsilon \text{Exp}(\frac{1}{6}(\log \log t_0 + 13) + \frac{9}{6} \log \log t_0)(1 - \sigma_0))
\]

\[
= \varepsilon \text{Exp}(\frac{1}{6} r a)(10 \log \log t_0 + 13))
\]

The average of the sum over primes is

\[
\leq S = \sum p^{-\sigma_0} \text{Exp}(-\frac{P}{E})
\]
where \( Z = \text{Exp}(\frac{1}{2}(10 \log \log t_0 + 13)) \), since \( Z \geq \) maximum value of \( X \) during the averaging. Now

\[
S \leq \sum_{p \leq 2} p^{-s_0} + \sum_{p > 2} Z_p^{p-1-s_0} = S_1 + S_2 \text{ say.}
\]

Here

\[
S_1 \leq Z^{1-s_0} \sum_{p \leq 2} \frac{1}{p} \text{ and } S_2 \leq \varepsilon Z^{1-s_0},
\]

where \( \varepsilon > 0 \) is an arbitrary constant. We have

\[
\sum_{p \leq 2} \frac{1}{p} \leq \log \log Z + \gamma - \sum_{p,m \geq 2} (mp^n)^{-1} + \varepsilon
\]

where \( \varepsilon > 0 \) is an arbitrary constant (see [11], p.58, Equation (3.14.5)) and \( \gamma \) is the Euler's constant. Hence

\[
| \log \zeta(s_0) | \leq O(1) + \varepsilon Z^{1-s_0} + Z^{1-s_0} (\log \log Z + \gamma - \alpha + \varepsilon) \text{ where } \alpha = \sum_{p,m \geq 2} (mp^n)^{-1}.
\]

Therefore

\[
| \zeta(s_0) | \ll \text{Exp}(Z^{1-s_0} (\log \log Z + 1)).
\]

This completes the proof of Theorem 5.

ACKNOWLEDGEMENT. This work was done while the authors met for a month in Ramanujan Institute, Madras. The authors are thankful to Professor K.S. Padmanabhan and Professor M.S. Rangachari for providing us a nice atmosphere for this work. Finally the authors are also thankful to Professor A. Ivić for encouragement.

If \( k > 0 \) is an integer then by the method of § 5 the following improvement of equation (3) can be proved under the only assumptions \( 0 < \delta \leq 1, \) \( | f(s_1 + w) | \leq M, (M \geq \delta) \) in \( | w | \leq 10\delta, \) and \( | \sigma - \sigma_1 | \leq \delta (\log M)^{-1}. \) Then \( I(\sigma) \log M \) on the RHS can be replaced by \( \delta^{-1} I(\sigma) \log M. \) The implied constant in \( \ll \) would then be independent of \( \delta. \) Professor A. Ivić pointed out that the method of § 5 allows one to take \( H = 1 + \delta \) in Theorem 3. The authors then succeeded in proving the above improvement.

POST-SCRIPT. In all the equations marked with an asterisk there is no change if \( k \) is an integer. But if \( k \) is not an integer there will be a loss of a \( \log \log \) factor. To see this we apply (3) and (3') with the last remark in Theorem 2. Thus if \( k \) is not an integer, we have for any constant \( \sigma \) in \( a < \sigma < b \) (and \( 2\delta \) in place of \( \delta \)),

\[
| f(\sigma + it) | \leq M^{-\delta} + I(\sigma) \log M \log \log M.
\]

(But if \( k \) is an integer \( \log \log M \) on RHS can be dropped provided in place of \( \delta \) we choose a large constant). It will be nice if we can remove \( \log \log M \) even if \( k \) is not an integer.
