A NOTE
TO A PAPER BY RAMACHANDRA ON
TRANSCENDENTAL NUMBERS

By

K. RAMACHANDRA AND S SREENIVASAN

PROFESSOR Th. SCHNEIDER ON HIS SEVENTIETH
BIRTHDAY

§ 1 Introduction

A typical result proved is that out of the numbers
$$2^n \quad (n = 1, 2, \ldots, N)$$
the number of algebraic numbers does not exceed
$$\frac{1}{2} + \sqrt{(4N - 4 + \frac{1}{4})}$$
The same bound is true for the numbers
$$t^n$$
where $t$ is any transcendental number and more generally of the numbers
$$\text{Exp} (\mathcal{A} t^n)$$
where $\mathcal{A}$ is any non-zero complex number. Next if $\wp (z)$ is any Weierstrass elliptic function with algebraic invariants $g_2, g_3$ the corresponding bound for the numbers
$$\wp \left( \mathcal{A} t^n \right)$$
is
$$\frac{1}{2} + \sqrt{(8N - 8 + \frac{1}{4})}$$
(Here the value $\wp$ of $\wp (z)$ is regarded as algebraic by convention). Actually our argument in § 2 shows that the number of algebraic numbers in
$$2^n \quad (n = M+1, M+2, \ldots, M+N)$$
does not exceed
$$\frac{1}{2} + \sqrt{(4N - 4 + \frac{1}{4})}$$
and similar results in other cases stated above. We show that these results are easy corollaries to the following Theorem (see [2]).
Theorem

(1) Let $a$ and $b$ be non-zero complex numbers such that $\frac{a}{b}$ is irrational. Let $d_1$, $d_2$, $d_3$ be complex numbers such that $t_1 d_1 + t_2 d_2 + t_3 d_3 = 0$ ($t_1, t_2, t_3$ integers) is possible only when $t_1 = t_2 = t_3 = 0$. Then at least one of the six numbers $\exp(a d_1)$, $\exp(b d_1)$ ($l = 1, 2, 3$) is transcendental.

(2) Let $a$ and $b$ be non-zero complex numbers such that $\frac{a}{b}$ is irrational. Let $d_1$, $d_2$, ..., $d_5$ be complex numbers such that $t_1 d_1 + t_2 d_2 + \cdots + t_5 d_5 = 0$ ($t_1, \ldots, t_5$ integers) is possible only when $t_1 = t_2 = \ldots = t_5 = 0$. Then at least one of the ten numbers $\exp(a d_1)$, $\exp b d_1)$, ($l = 1$ to 5) is transcendental.

Remarks

The first part of the Theorem is originally due to Siegel, Schneider, and Gelfond (see Problem 1 on page 138 of [4]). The first part was rediscovered and the second part was proved by K. Ramachandra in his paper [2], by developing the method of Siegel, Schneider, and Gelfond. Some progress in the direction of the Theorem was made (around the same time) independently by S. L10g, who in particular rediscovered the first part of the Theorem (see page 119 of A. Baker's book [1]).

§ 2 Proof of the Results

We first prove the following Lemma.

Lemma

Let $S$ be a non-empty set of natural numbers and $S(N, M)$ the sub-set of those natural numbers contained in $[M, M + N - 1]$, (where $M$ and $N$ are any two natural numbers) Suppose that
for every non-zero integer \( r \), the equation 
\[ x + r = y, \quad (x, y \text{ in } S), \]
does not have more than \( D \) solutions (where \( D \) is a natural number independent of \( r \)). Let \( f(N, M) \) be the number of natural numbers in \( S(N, M) \). Then there holds,
\[ f(N, M) \leq \frac{4}{3} + \sqrt{2DN - 2D + \frac{1}{4}}. \]

**Proof**

Let \( g(r, N, M) \) denote the number of solutions of the equation in the Lemma with the restriction that \( x, y \) should be in \( S(N, M) \). Then
\[
(f(N, M))^2 = \sum_{(N-1) \leq r \leq N-1} g(r, N, M)
= \sum_{r = 0}^{\infty} g(r, N, M)
= f(N, M) + 2D(N - 1).
\]

This proves the Lemma completely.

Using the lemma our results can be deduced easily from the Theorem as follows. Take \( S \) to be the set of those natural numbers for which \( \exp(\alpha_1^n) \) is algebraic. We take \( M = 1 \).

In the first part of the Theorem we take \( a = \alpha, b = \alpha e^r \).
Then the Theorem tells us that we can take \( D = 2 \). For our assertions about \( \phi(z) \) we can take \( a = \alpha, b = \alpha e^r \). Then the Theorem tells us that we take \( D = 4 \).

This proves our assertions completely.

**Remark**

In a paper to appear [3], R. Balasubramanian and K. Ramachandra prove that the number of algebraic numbers among \( 2^{\pi}, 2^{2\pi}, \ldots, 2^{N\pi} \) is \( \sqrt{2N(1 + o(1))} \). They also prove similar improvements of results in section 2.
§ 3. Further Results. The Gelfond-Siegel-Schneider method
(of proving the transcendence of \(e^\pi\) and \(2^{\sqrt{2}}\)) was developed
in a deep way by Gelfond to prove the algebraic independence
of \(2^\beta\) and \(2^{\beta^2}\) where \(\beta = \sqrt{2}\). These researches of Gelfond
have been continued by R. Tijdeman, D. Brownawell, and
M. Waldschmidt. More profound results have been obtained by
G. V. Choodnovskii and we now quote a result from his paper:
Algebraic independence of values of exponential and elliptic
functions (Proceedings of the International Congress of
\(\alpha_1, \ldots, \alpha_M\) be complex numbers linearly independent over the
rationals and let \(\beta_1, \beta_2, \ldots, \beta_N\) be complex numbers linearly
independent over the rationals where \(M N \geq (n+1)(M+N)\),
\(M, N, \text{ and } n\) being fixed natural numbers. Then at least \(n+1\)
of the \(MN\) numbers \(\exp(\alpha_i \beta_j)\) are algebraically independent.

Let \(\tau\) be any fixed transcendental number and let \(t_1, \ldots, t_n\) be
any \(n\) fixed algebraically independent complex numbers.
Let \(\alpha\) be a fixed non-zero complex number. Putting
\(\alpha_i = \alpha t_1^{r_i}, \beta_i = \alpha t_1^{m_j}\), where \(r_i\) \((i = 1\) to \(M)\) are any
non-zero distinct integers and \(m_j\) \((j = 1\) to \(N)\) are distinct
natural numbers, we deduce the following corollary. Let \(S\)
be the set of those natural numbers \(m\) for which \(\exp(\alpha t_1^m)\)
depends algebraically on \(t_1, \ldots, t_n\) and further let \(S_0\) be the set
of those numbers in \(S\) which satisfy \(x < m < x + y\), where
\(x > 1, y > 1\). We now set \(M = n + 2\) and by choosing \(N\) to
be a large constant and \(m_j\) to be in \(S_0\) we deduce that one at
least of the numbers \(\exp(\alpha t_1^{r_i} + m_j)\) does not belong to \(S_0\).

From this we deduce that the number of integers in \(S_0\) does
not exceed $C \theta^2$ where $\theta = 1 - \frac{1}{n+3}$, and $C$ depends only on $n$. The last deduction is facilitated by the following lemma which is an extension of the lemma proved in section 2.

**Extension**

Let $k$ be a natural number and $S_0$ a subset of natural numbers consisting of at least two and at most finitely natural numbers. Consider the difference set $R$ consisting of all non-zero differences of numbers in $S_0$. Let $T$ be any non-empty subset of $R^k$, the set of all possible $k$-tuples of numbers in $R$. For any integer $r$ in $R$, put $S_r = \{ a | a \in S_0, a + r \in S_0 \}$. Now for $r = (r_1, \ldots, r_k)$ in $R^k$ put $S_r = S_{r_1} \cap \cdots \cap S_{r_k}$.

Then

$$\sum_{r \in T} \sum_{a \in S_r} 1 = \sum_{r \in T} \sum_{a \in S_0} \sum_{r \in T, S_r \text{ containing } a} 1$$

and the L. H. S. is not more than $(\max_{r \in T} \sum_{a \in S_r} 1) \sum_{r \in T} 1$. Further if $T$ consists of all possible $r = (r_1, \ldots, r_k)$, where $r_1, \ldots, r_k$ are distinct then R. H. S. here is $\Rightarrow$ and $\Leftarrow$ $(\exists 1)^{k+1}$ where the implied constants depend only on $k$.

**Remark**

Taking $k = n + 2$ and $S_0$ as described before the extension we get the result stated since $\max_{r \in T} \sum_{a \in S_r} 1$.
bounded by a constant depending only on \( n \) by the deep result of Choodnovski.

Proof of the extension follows by interchanging the summation. The bounds for the L. H. S. comes from the fact that \( \chi \) is closely related to the number of combinations of \( \binom{\chi + 1}{k} \), taken \( k \) at a time.

We now state the final result which we have deduced as an easy corollary to the deep result of G. V. Choodnovski

Final Result

Let \( \alpha, t_1, \ldots, t_n \) be \( n+1 \) non-zero complex numbers where \( n \) is a fixed natural number. Let \( m \) run through those natural numbers for which \( \text{Exp}(\alpha t^m) \) (\( t \) being a fixed transcendental number) depends algebraically on \( t_1, \ldots, t_n \). Put \( N(m) = \chi + 1 \). Then \( N(x+y) - N(x) \) does not exceed \( C y^\Theta \) \( m \leq x \) where \( \Theta = 1 - \frac{1}{n+3} \) and \( C \) is an effective positive constant depending only on \( n \). Here as usual \( x > 1 \), and \( y > 1 \).

Remark 1

When \( t_1, \ldots, t_n \) are algebraic numbers the results of section 2 are better.

Remark 2

This note began with the observation that in section 2 the set \( S \) does not contain any sub-set with \( D+1 \) elements in arithmetical progression (this follows immediately from the Theorem) and so by Szemeredi's Theorem \( f(N, 1) = o(N) \). Next in a correspondence with us Professor R. Tijdeman pointed out that it is possible to use Roth's theorem in the
direction of Szemeredi's Theorem and get
\[ f(N, 1) = O \left( \frac{N}{\log \log N} \right). \]

**Remark 3**

It is possible to reduce \( \Theta \) to \( 1 - \frac{1}{n+2} \) in the final result.

**Remark 4**

The lemma can be improved slightly. In particular the number of algebraic numbers among \( 2^\pi, 2^{2^\pi}, \ldots, 2^{2^2} \) is \( \ll 2/\log N \).

**Remark 5.**

Let \( \phi(N) \) be the number of transcendental numbers of the form \( 2^n \) where \( 1 \leq n \leq N \) and it is a fixed transcendent. If \( f(n) = n^2 \) then \( \phi(N) = (1 + O \left( \sqrt{\frac{2 \log \log N}{\log N}} \right))^N \). This is a consequence of the fact that the number of integers in \( \left( -N^2, N^2 \right) \) which have at most two representations of the form \( f(n_1) - f(n_2) (n_1 \neq n_2) \) is \( O \left( \frac{N^2 \log \log N}{\log N} \right) \). Next since there is a positive integer which is a difference of 2 positive cubes in 3 different ways it follows that if \( f(n) = n^3 \), \( \phi(N) \gg N \) for \( N > 10^{30} \).

Starting from \( 37 = 4^3 - 3^3 = \left( \frac{10}{3} \right)^3 - \left( \frac{1}{3} \right)^3 \) we get by the chord process a new point. The tangent process at this point gives \( (19 \left( 19^3 + 2 \cdot 18^3 \right))^3 - (18 \left( 2 \cdot 19^3 + 18^3 \right))^3 = (7 \left( 19^3 - 18^3 \right))^3 \cdot 37. \)
